

Circa is a powerful and sophisticated estimation and planning application for scheduling, managing, tracking and controlling software projects

Define project terms of reference, set project calendar and configure project properties. Password protect sensitive project information. Import and export project settings as templates to share information between projects.

Understand requirements and scope the application using software artifacts. Import software using XML from UML CASE tools or auto populate to produce rapid first-cut estimates.

Specify production artifacts to take account of creative content and production activities such as help systems, product branding, hardware integration and training.

Define resources and profile their skills. Import resource information from MS Project. Allocate resources to project teams. Establish the best team size using the optimum resource chart.

Identify and assess risk to derive contingency. View a risk chart to ascertain the probability of project completion within a given timeframe.

Produce estimates of effort, person-days, duration and cost for each task, iteration, phase and for the entire project. Monitor project progress and compare actual values against estimates.

Define a project process and schedule work. Allocate artifacts and workers to tasks. Define task dependencies and set the status of tasks (planned, in progress or complete). View the project schedule as a Gantt chart and export to MS Project.

Log defects in software or production activities. Assess time and effort associated with correcting and re-testing project defects.

Use built-in productivity metrics to drive estimates of software effort. Adjust metrics to increase estimate accuracy over time. Set-up technology metrics to take account of their impacts.

Produce detailed management information reports in HTML and MS Excel formats. Run a project validation report to check key project indicators.
